Statistical testing

Null hypothesis
$H_0$: no effect

All other assumptions

Significance level
$\alpha = 0.05$

$p$-value: probability that the observed effect is random

$p < \alpha$
Reject $H_0$
Effect is real

$p \geq \alpha$
Insufficient evidence

Test statistic $T_{\text{obs}}$
One-sample t-test
One-sample t-test

Null hypothesis: the sample came from a population with mean $\mu = 20 \text{ g}$
t-statistic

- Sample $x_1, x_2, \ldots, x_n$

  $M$ - mean
  $SD$ - standard deviation
  $SE = SD/\sqrt{n}$ - standard error

- From these we can find
  \[ t = \frac{M - \mu}{SE} \]

- more generic form:
  \[ t = \frac{\text{deviation}}{\text{standard error}} \]
Note: Student’s $t$-distribution

- $t$-statistic is distributed with $t$-distribution

- Standardized

- One parameter: degrees of freedom, $\nu$

- For large $\nu$ approaches normal distribution

**THE PROBABLE ERROR OF A MEAN.**

**By Student.**

*Introduction.*

Any experiment may be regarded as forming an individual of a “population” of experiments which might be performed under the same conditions. A series of experiments is a sample drawn from this population.

Now any series of experiments is only of value in so far as it enables us to form a judgment as to the statistical constants of the population to which the experiments belong. In a great number of cases the question finally turns on the value of a mean, either directly, or as the mean difference between the two quantities.

If the number of experiments be very large, we may have precise information as to the value of the mean, but if our sample be small, we have two sources of uncertainty:—(1) owing to the “error of random sampling” the mean of our series of experiments deviates more or less widely from the mean of the population, and (2) the sample is not sufficiently large to determine what is the law of distribution of individuals. It is usual, however, to assume a normal distribution, because, in a very large number of cases, this gives an approximation so close that a small sample will give no real information as to the manner in which the population deviates from normality: since some law of distribution must be assumed it is better to work with a curve whose area and ordinates are tabulated, and whose properties are well known. This assumption is accordingly made in the present paper, so that its conclusions are not strictly applicable to populations known not to be normally distributed; yet it appears probable that the deviation from normality must be very extreme to lead to serious error. We are concerned here solely with the first of these two sources of uncertainty.
Null distribution for the deviation of the mean

Population of mice
\( \mu = 20 \text{ g}, \sigma = 5 \)

Select sample size 5

\[
Z = \frac{M - \mu}{\sigma/\sqrt{n}}
\]

\[
t = \frac{M - \mu}{SD/\sqrt{n}}
\]

Build distributions of \( M, Z \) and \( t \)
Null distribution for the deviation of the mean

Original distribution

$N(\mu, \sigma)$

Distribution of $Z$

$N(0, 1)$

Distribution of $M$

$N\left( \mu, \frac{\sigma}{\sqrt{n}} \right)$

Distribution of $t$

$N(0, 1)$
Null distribution for the deviation of the mean

\[ Z = \frac{M - \mu}{\sigma/\sqrt{n}} \]

\( \sigma \) - population parameter (unknown)

\[ t = \frac{M - \mu}{SD/\sqrt{n}} = \frac{M - \mu}{SE} \]

\( SD \) - sample estimator (known)
One-sample t-test

- Consider a sample of $n$ measurements
  - $M$ – sample mean
  - $SD$ – sample standard deviation
  - $SE = SD / \sqrt{n}$ – sample standard error

- Null hypothesis: the sample comes from a population with mean $\mu$

- Test statistic
  \[ t = \frac{M - \mu}{SE} \]

- is distributed with t-distribution with $n - 1$ degrees of freedom

null distribution

$t$-distribution with 4 d.o.f.

Null distribution represents all random samples when the null hypothesis is true
One-sample t-test: example

- $H_0: \mu = 20$ g
- 5 mice with body mass (g):
  - 19.5, 26.7, 24.5, 21.9, 22.0

$$M = 22.92 \text{ g}$$
$$SD = 2.76 \text{ g}$$
$$SE = 1.23 \text{ g}$$

$$t = \frac{22.92 - 20}{1.23} = 2.37$$
$$\nu = 4$$

$$p = 0.04$$
Sidedness

One-sided test
$H_1: M > \mu$

Two-sided test
$H_2: M \neq \mu$

Observation
$p_1 = 0.04$

$p_2 = 2p_1$

$p_2 = 0.08$
Normality of data

Original distribution

Distribution of t

How to do it in R?

# One-sided t-test
> mass = c(19.5, 26.7, 24.5, 21.9, 22.0)
> t.test(mass, mu=20, alternative="greater")

    One Sample t-test

data:  mass
  t = 2.3697, df = 4, p-value = 0.03842
alternative hypothesis: true mean is greater than 20
95 percent confidence interval: 20.29307    Inf
sample estimates:
mean of x
     22.92
Two-sample t-test
Two samples

- Consider two samples (different sizes)
- Are they different?
- Are their means different?
- Do they come from populations with different means?

\[
\begin{align*}
\text{English:} & \quad n_E = 12, \quad M_E = 19.0 \text{ g}, \quad S_E = 4.6 \text{ g} \\
\text{Scottish:} & \quad n_S = 9, \quad M_S = 24.0 \text{ g}, \quad S_S = 4.3 \text{ g}
\end{align*}
\]
Gedankenexperiment: null distribution

Population of British mice
\( \mu = 20 \text{ g}, \sigma = 5 \text{ g} \)

Select two samples size 12 and 9

\[ t = \frac{M_E - M_S}{SE} \]

Build distribution of \( \Delta M \) and \( t \)

Normal population
\( \mu = 20 \text{ g}, \sigma = 5 \text{ g} \)

Population of British mice
\( \mu = 20 \text{ g}, \sigma = 5 \text{ g} \)

Select two samples size 12 and 9

\[ t = \frac{M_E - M_S}{SE} \]

Build distribution of \( \Delta M \) and \( t \)

\( \times 1,000,000 \)

\( \Delta M \)
Null distribution

- *Gedankenexperiment*

- Test statistic

\[ t = \frac{M_1 - M_2}{SE} \]

is distributed with t-distribution with \( v \) degrees of freedom.

Null distribution represents all random samples when the null hypothesis is true.
Null distribution

- *Gedankenexperiment*

- Test statistic

\[ t = \frac{M_1 - M_2}{SE} \]

is distributed with t-distribution with \( \nu \) degrees of freedom

Null distribution represents all random samples when the null hypothesis is true
Two-sample t-test

- Two samples of size $n_1$ and $n_2$
- Null hypothesis: both samples come from populations of the same mean
  - $H_0: \mu_1 = \mu_2$
- Find $M_1$, $M_2$ and $SE$
- Test statistic
  \[
  t = \frac{M_1 - M_2}{SE}
  \]
  is distributed with t-distribution with $\nu$ degrees of freedom
- How do we find $SE$ from two samples?

<table>
<thead>
<tr>
<th></th>
<th>$n$</th>
<th>$M$</th>
<th>$SD$</th>
</tr>
</thead>
<tbody>
<tr>
<td>English</td>
<td>$n_E = 12$</td>
<td>$M_E = 19.0$ g</td>
<td>$SD_E = 4.6$ g</td>
</tr>
<tr>
<td>Scottish</td>
<td>$n_S = 9$</td>
<td>$M_S = 24.0$ g</td>
<td>$SD_S = 4.3$ g</td>
</tr>
</tbody>
</table>
Case 1: equal variances

- Assume that both distributions have the same variance (or standard deviation)

- Use pooled variance estimator:

\[ SD_{1,2}^2 = \frac{(n_1 - 1)SD_1^2 + (n_2 - 1)SD_2^2}{n_1 + n_2 - 2} \]

- And then the standard error and the number of degrees of freedom are

\[ SE = SD_{1,2} \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} \]

\[ \nu = n_1 + n_2 - 2 \]

In case of equal samples sizes, \( n_1 = n_2 = n \), these equations simplify:

\[ SD_{1,2}^2 = \frac{1}{2} (SD_1^2 + SD_2^2) \]

\[ SE = \frac{SD_{1,2}}{\sqrt{n}} \]

\[ \nu = 2n - 2 \]
Case 1: equal variances, example

\begin{align*}
n_E &= 12 \\
M_E &= 19.04 \text{ g} \\
SD_E &= 4.61 \text{ g} \\
n_S &= 9 \\
M_S &= 23.99 \text{ g} \\
SD_S &= 4.32 \text{ g} \\
SD_{1,2} &= 4.49 \text{ g} \\
SE &= 1.98 \text{ g} \\
v &= 19
\end{align*}

\[ t = \frac{23.99 - 19.04}{1.98} = 2.499 \]

\[ p = 0.011 \text{ (one-sided)} \]

\[ p = 0.022 \text{ (two-sided)} \]

\[ > 1 - pt(2.499, 19) \]

[1] 0.01089314
Case 2: unequal variances

- Assume that distributions have different variances
- Welch’s t-test

- Find individual standard errors (squared):

\[ SE_1^2 = \frac{SD_1^2}{n_1} \quad SE_2^2 = \frac{SD_2^2}{n_2} \]

- Find the common standard error:

\[ SE = \sqrt{SE_1^2 + SE_2^2} \]

- Number of degrees of freedom

\[ v \approx \frac{(SE_1^2 + SE_2^2)^2}{SE_1^4/n_1 - 1 + SE_2^4/n_2 - 1} \]
Case 2: unequal variances, example

\[ n_E = 12 \]
\[ M_E = 19.04 \text{ g} \]
\[ SD_E = 4.61 \text{ g} \]

\[ n_S = 9 \]
\[ M_S = 23.99 \text{ g} \]
\[ SD_S = 4.32 \text{ g} \]

\[ SE_E^2 = 1.77 \text{ g}^2 \]
\[ SE_S^2 = 2.07 \text{ g}^2 \]
\[ SE = 1.96 \text{ g} \]
\[ \nu = 18.0 \]
\[ t = \frac{23.99 - 19.04}{1.96} = 2.524 \]

\[ p = 0.011 \text{ (one-sided)} \]
\[ p = 0.021 \text{ (two-sided)} \]
What if variances are not equal?

- Say, our samples come from two populations:
  - English: \( \mu = 20 \text{ g}, \quad \sigma = 5 \text{ g} \)
  - Scottish: \( \mu = 20 \text{ g}, \quad \sigma = 2.5 \text{ g} \)

- ‘Equal variance’ t-statistic does not represent the null hypothesis

- Unless you are certain that the variances are equal, use the Welch’s test
P-values vs. effect size

\[ n = 8 \]
\[ \Delta M = 6.3 \text{ g} \]
\[ p = 0.02 \]

\[ n = 100 \]
\[ \Delta M = 1.8 \text{ g} \]
\[ p = 0.02 \]
P-value is not a measure of biological significance.
## Two-sample t test: summary

95 percent confidence interval:
  0.1443915      Inf
sample estimates:
mean of the differences
  0.4625
```
F-test
Variance

- One sample of size $n$
- Sample variance

$$SD^2_{n-1} = \frac{1}{n-1} \sum_i (x_i - M)^2$$

- Generalized variance: mean square

$$MS = \frac{SS}{\nu}$$

- where
  - $SS$ - sum of squared residuals
  - $\nu$ - number of degrees of freedom
Comparison of variance

- Consider two samples
  - English mice, \( n_E = 12 \)
  - Scottish mice \( n_S = 9 \)

- We want to test if they come from the populations with the same variance, \( \sigma^2 \)

- Null hypothesis: \( \sigma_1^2 = \sigma_2^2 \)

- We need a test statistic with known distribution

\[
\begin{align*}
  n_E &= 12 \\
  SD_E^2 &= 21 \text{ g}^2 \\
  n_S &= 9 \\
  SD_S^2 &= 19 \text{ g}^2
\end{align*}
\]
Gedankenexperiment

Population of British mice
\( \mu = 20 \text{ g}, \sigma = 5 \)

Select two samples size 12 and 9

\[ F = \frac{SD_E^2}{SD_S^2} \]

Build distribution of \( F \)

null distribution

Null distribution represents all random samples when the null hypothesis is true
Test to compare two variances

- Consider two samples, sized \( n_1 \) and \( n_2 \)

- Null hypothesis: they come from distributions with the same variance
  \[ H_0: \sigma_1^2 = \sigma_2^2 \]

- Test statistic:
  \[ F = \frac{SD_1^2}{SD_2^2} \]

  is distributed with F-distribution with \( n_1 - 1 \) and \( n_2 - 1 \) degrees of freedom

Reminder
Test statistic for two-sample t-test:
\[ t = \frac{M_1 - M_2}{SE} \]

F-distribution, \( \nu_1 = 11, \nu_2 = 8 \)

Null distribution represents all random samples when the null hypothesis is true
F-test

- English mice: $SD_E = 4.61 \, g, n_E = 12$
- Scottish mice: $SD_S = 4.32 \, g, n_S = 9$

Null hypothesis: they come from distributions with the same variance

Test statistic:

$$F = \frac{4.61^2}{4.32^2} = 1.139$$
$$\nu_E = 11$$
$$\nu_S = 8$$
$$p = 0.44$$

F-distribution, $\nu_1 = 11, \nu_2 = 8$

Observation

Density

$p = 0.44$

> 1 - pf(1.139, 11, 8)
